

SIKA-R...IS/AS

Filter Technology

Since 1759

> 250 years of exceptional engineering

GKN Sinter Metals Filters, the leading manufacturer of porous sinter metal products, offers a variety of solutions to fulfil customer requirements.

We are familiar with various applications in almost every industrial branch.

Our products are applied in gas- and liquid filtration, dampening, sparging, sensor protection, bulk handling and many more. We offer solutions for high temperature and corrosive environments.

Sintered filter elements made of stainless steels, bronze, nickel based alloys, titanium and several special alloys can be manufactured seamless up to 1500 mm length and 320 mm OD. Larger elements will be assembled in our certified in-house welding shop.

Our most innovative product for the chemical industry is the patented metallic membrane SIKA-R...AS.

The filter cartridges equipped with this state-of-the-art technology offer a flow rate up to 4 times higher compared to conventional sinter metal filter cartridges. Furthermore an excellent back flush performance is guaranteed. The filter active membrane layer with filter grades down to 0.1 µm absolute has a thickness of only 200 µm and is made of the same alloy as the coarse support material. The membrane is sinter bonded to the support and therefore cannot peel off.

Another innovation introduced by GKN is the sinter bonded joint of porous parts with solid fittings in order to avoid welding seams – the weak spot of all sintered cartridges of our competitors.

All sintered materials of GKN offer a self-supporting structure with high mechanical strength.

We manufacture various filter grades with specified pore sizes and flow rates in order to have the appropriate solution for your requirements.

Filter-Elements

High Porosity Sintered Materials

SIKA-R...IS

SIKA-R...IS, a trademark of GKN Sinter Metals Filters, is our brand name for high porous stainless filter elements manufactured by our isostatic compaction process.

Metal Membranes

SIKA-R...AS

SIKA-R...AS, a trademark of GKN Sinter Metals Filters, is our brand name for high porous asymmetric metallic membranes.

SIKA-R...IS/AS materials are used as self-supporting structural elements. The pores are mechanically fixed regarding size and position after the sintering process.

Properties

These characteristics go along with the following important properties of SIKA products:

- Shape-stability, i.e. self-supporting structural elements suitable for high differential pressures and pressure swings
- Particularly good properties under compression, vibration and changing conditions or with high impulse pressures
- High heat resistance and thermal stability up to 900°C
- High permeability with low pressure drop
- Precise filtration because of homogeneous pore size distribution
- Chemical resistance against acids and caustic solutions in various aggressive media
- Backflushing and easy cleaning with supersaturated superheated steam, chemical solvents, thermal and ultrasonic processes
- The variety of materials used can be welded, soldered and machined

Improved Properties of ASymmetric Filters Compared to Conventional (Symmetric) Filters

Asymmetric design allows manipulation of stability and particle retention functions which are independent.

As a result of this optimal combination, metallic SIKA-R...AS membranes truly impress.

SIKA-R...AS elements have the following features which are particularly advantageous in rigorous every day applications:

- Up to 4-times increase in permeability performance
- Improved back-flushing properties, resulted out of reduced pressure drop
- Filtration in the sub-micrometer-range
- Significant increase in service life
- Economical use
- No filter cake needed for clear filtration

The asymmetric metallic membrane can be manufactured in tube or disc shape.

The filter layer is applied either to the inner or outer surface of the tube.

The application, whether outside - in or inside - out, determines the configuration.

Standard wall-thicknesses are 1.5 mm, 2 mm and 3 mm.

The filter effective layer of 0.2 mm is sintered on the support.

Naturally all the advantages that characterize metallic filter elements are also true for SIKA-R...AS. The metallic membrane is dimensionally stable, resistant to fluctuating mechanical loading and thermal stress, can be used at high temperatures and in corrosive media.

Applications

SIKA-R...IS and SIKA-R...AS are employed in:

- Catalyst separation and recovery
- Refinery applications
- Gas- and Liquid filtration
- Aerosol separation
- Sparging
- Fluidization
- Air bearings for polymer sheet production
- Silencing

as well as in other fields of chemical and food processing industries, power engineering and environmental technology.

Further Applications of SIKA-R...AS

Metallic membranes can be used for various filtration jobs in chemical, food and pharmaceutical industries, also process engineering. Additionally, the energy and environmental sectors also use such elements.

The following is an exemplary list of keywords:

- Catalyst recovery in the chemical industry
- Cross-flow filtration
- Gas filtration
- Liquid filtration
- Analytical devices
- Medical devices
- Vegetable oil

Manufacturing of SIKA-R.../S and SIKA-R.../AS Products

Compaction

SIKA-R.../S filter elements are formed by cold isostatic pressing.

For the compaction process the metal powder is filled into the compaction tool which consists of a solid steel core and oversized outer rubber sleeve.

After sealing the filled assembly it is submerged into a vessel of hydraulic fluid.

The next step is to apply pressure onto the fluid which moves the outer rubber sleeve towards the steel core and forms the porous part by compressing the powder in between.

Due to the uniformity of the hydro pressure the porous element excels by its uniform porosity with homogeneous physical characteristics and properties over the complete part.

Sizes that can be achieved are up to 1600 mm length and 320 mm diameter.

Filling

Pressing

Sintering

The compacted part is sintered in specially designed furnaces.

Sintering is the fundamental processing step for all Powdered Metal (P/M) products. It is the process of bonding the powder particles by fusing them together at temperatures well below their melting point.

After sintering, regardless of micron size, the separate grain structure of the original powdered metal becomes fully interlinked to form a rigid part.

Sintering gives the high porous material the shape stability and property of a strong metal component.

Solid Connection

Furthermore, GKN owns specific know-how to integrate a solid connection fitting into the porous part prior to the pressing process.

Due to the sintered joint, any further porous to solid welding seams are avoided. This increases the strength and the reliability of the porous elements.

Further treatment of SIKAR...AS products

SIKA-R...AS denotes asymmetrically constructed metallic membranes.

Coating technique

The metal membrane is produced by applying a layer of extremely fine metal powder onto carrier of coarser porosity, such as the standard sinter products of SIKAR...IS or SIKAR...AX.

The subsequent sintering produces an even metal coating of approximately 200 µm thickness so firmly bonded to the carrier as to exclude cracking and flaking in the layer.

Compared to the carriersupport, the sintered layer has significantly smaller pore size, so that during filtration particulate matter is retained on the filter coating surface. The support structure (carrier) has no discernible influence on the filtration process and merely serves to ensure pressure loss remains low.

As a result of years of development, the product offers users a sintered membrane that combines high permeability and very low pressure drop, yet retaining all the advantages of sintered metal filters.

Filter Elements

High Porosity Sintered Materials SIKA-R.../S and SIKA-R...AS

All types of GKN-SIKA filter elements have following salient features:

- seamless construction up to 1,500 mm length
- seamless construction up to 320 mm diameter
- seamless assembly of solid flange and porous tube
- threads according to customers' requirement

The construction without welding seams in the porous material provides best corrosion resistance and the fatigue strength is considerably higher compared to conventional welded constructions.
